

LINUX PRACTICAL — UNIT I & UNIT II

15 Scenario-Based Practice Questions

1. File System Navigation

Starting from your home directory, display the current working directory, move to /etc, list its contents in long format, then move to /var/log and return to your home directory.

2. File Searching

Using a single command, locate all regular files ending with .conf under /etc. Suppress permission-denied messages and display only the matching paths.

3. Directory and File Creation

Create the following directory structure in your home directory:

LinuxAssessment/

 commands/

 reports/

 backup/

Inside commands, create three empty files named cmd1.txt, cmd2.txt, and cmd3.txt. Verify the structure.

4. Shell Expansion

Create files with the following names:

data1.txt

data2.txt

data3.txt

report1.txt

report2.txt

Using pathname expansion, display only the files beginning with data and then only the files beginning with report.

5. Redirection and Appending

Create a file named linux_commands.txt from the shell and store at least five Linux commands in it. Display its contents and then append three additional commands without overwriting the existing content.

6. Getting Help

Find the manual page for chmod. Display the section containing its command-line options and identify how you can search installed documentation for a particular keyword.

7. User and Group Management

Create a group named developers and two users named developer1 and developer2. Add both users to developers as supplementary group members and verify their group membership.

8. Password and User Information

Create a local user named labuser, assign a password, and display information about the account including its UID, primary group, home directory, and login shell.

9. File Permissions

Create a file named project.txt and configure its permissions so that:

Owner → read + write

Group → read

Others → no permission

Verify the resulting permission string.

10. Directory Permissions

Create a directory named shared_lab and configure its permissions so that the owner has full access, the group has read and execute access, and others have no access. Verify the permissions.

11. Process Management

Start a long-running foreground process, suspend it, place it in the background, display the active jobs, and then bring the process back to the foreground.

12. Process Monitoring and Termination

Display processes running under your current user. Identify the PID of one process that you started and terminate it gracefully using its PID. Verify that the process has stopped.

13. Service Management

Check the status of the SSH service using systemctl. Configure the service to start automatically at boot and verify that it is enabled.

14. SSH and Remote Shell

From the RHEL system, use SSH to connect to localhost. After connecting, verify the username, hostname, and current working directory. Exit the SSH session and verify that you have returned to the original shell.

15. Logs and Troubleshooting

Use journalctl to:

1. Display recent system log entries.
2. Display logs generated by the SSH service.
3. Display the most recent SSH-related entries first.
4. Identify any warning or error messages in the displayed output.

Exam Practice Pattern: Scenario → choose command → execute → verify the result.
